

SPECIFICATION

5 To Whom It May Concern:

Be it known that I, Jeffrey D. Marsh, a citizen of the United States of America, resident of St. Charles County, State of Missouri, whose full post office address is 7 Country Road, Foristell, Missouri, 63348, have invented new and useful improvements in and to:

BOOK TRIMMING APPARATUS AND METHOD

CROSS REFERENCE TO RELATED APPLICATION

This application claims priority to U.S. Provisional Patent Application No. 60/235,411, filed September 21, 2000.

BACKGROUND OF THE INVENTION

5 This invention relates to book trimming apparatus and a method of trimming a book along three edges of a perfect bound book using a single shear or trimming blade where the book is rotated to trim the three edges. Reference may be made to U. S. Patent 5,694,823.

SUMMARY OF THE INVENTION

10 Among the several objects and features of this invention may be noted the provision of a trimmer for trimming the margins along three edges of a perfect bound book which may be readily adjusted by an operator to trim any book within a range of sizes and thickness;

15 The provision of such a trimmer in which the operator may readily input the size (height and width) of the book into the control system for the computer, place the book in a book holder, and initiate operation of the trimmer so as to effect the trimming of three edges of the book to a predetermined size;

The provision of such a trimmer which accurately rotates the book as the trimmer moves the book to trim the three edges of the book;

20 The provision of such a trimmer which has a relatively small footprint so that it takes up a minimum amount of room in a print shop or the like;

The provision of such a trimmer which is easy to insert a book to be trimmed;

The provision of such a trimmer which trims the three edges of the book in a relatively short time; and

The provision of such a trimmer which is of rugged construction, which requires little operator training, and which accurately trims the edges of a book to predetermined 5 dimensions.

Briefly stated, a book trimmer of the present invention trims the edges of a perfect bound book to predetermined finished dimensions. The book is made up of a plurality of text pages and a cover with the book being rectangular. The margins of the book are to be trimmed along two of its minor edges and along one of its major edges to predetermined finished dimensions. The trimmer comprises a trimming blade movable between an open position in which the book may be inserted between the blade and a closed position in which the book is sheared between the blade and a platen along a shearing plane. The trimmer comprises a holder for gripping the book as the book is trimmed, and a carriage supporting the holder. The carriage is movable laterally with respect to the blade between a first position in which a first edge of the book may be trimmed, a second position in which a second edge of the book may be trimmed, and a third position in which a third edge of the book may be trimmed. The carriage along with the holder and the book carried by the holder are movable toward and away from the blade so as to position the book with respect to the blade such that the with the 15 carriage in its the first, second and third positions, the first, second and third edges of the book may be accurately positioned with respect to the shearing plane such that predetermined amounts of the book may be trimmed from the first, second and third 20

edges of the book thereby to produce a finished book trimmed to its predetermined finished dimensions.

Further, this invention comprises a method of trimming three edges of a perfect bound book to a predetermined finished size. The perfect bound book has a cover and 5 a plurality of pages with the book being generally rectangular and with the cover and pages being bound to one another along one edge or the spine of the book with the book having top and bottom edges being generally perpendicular to the spine and with an outer edge being generally parallel to the spine. More specifically, the method comprises placing the book to be trimmed in a holder with the bottom edge of the book projecting downwardly and with the book being gripped by the holder proximate the spine. Then moving the book vertically so that a predetermined amount of the book along its bottom edge is positioned for being trimmed from the book. A shear blade is then actuated to move in a generally shearing plane to trim the predetermined amount from the bottom edge of the book. The book is moved from the first position to a second position in which the top edge of the book projects toward the shearing plane. 15 The book is moved so that a predetermined amount of the book along the top edge is positioned for being trimmed from the book. The shear blade is actuated to trim the predetermined amount from the top edge of the book. The book is moved from the second position to a third position in which the side edge of the book is positioned so that a predetermined amount of the book along the side edge is positioned for being trimmed from the book. The shear blade is actuated to trim the predetermined amount from the side edge. Then, the trimmed book is released from the trimmer. 20

Other objects and features of this invention will be in part apparent and in part pointed out hereinafter.

RECORDED - SEPTEMBER 10 1990

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of the trimmer of the present invention;

Fig. 2 is a perspective of a perfect bound book to be trimmed by the trimmer of the present invention;

5 Fig. 3 is a perspective view of the trimmer with the cabinet removed illustrating a shear assembly, a carriage having a holder for holding the book as it is trimmed, and a first embodiment of an indexing mechanism for moving the carriage and the book between first, second and third positions for trimming a predetermined amount of the margins along the first and second minor edges and from one of the major edges of the book, and further illustrating a selectively operable screw jack for accurately adjusting the above mechanism and the book held thereby relative to the shear assembly;

Fig. 4 is a side elevation of the trimmer, as shown in Fig. 3, illustrating a book (shown in phantom) having its lower edge resting on the upper surface of a shear blade thereby to locate the book relative to the shear blade, and illustrating the first embodiment of the indexing mechanism for moving the book between its first, second and third position and for rotating the book so as to trim the edges of the book;

Fig. 5 is a perspective view of a sub-frame of the trimmer shown in Figs. 3 and 4 having a pair of spaced horizontal slide rods on which a carriage is slidably mounted with the carriage having a book holder pivotally mounted thereon and with the indexing 20 mechanism actuated so as to position the carriage in its first position so that a first of the minor edges of the book held by the book holder is generally parallel to the shearing plane of the shear plane, where the indexing mechanism is actuated by a double rod hydraulic actuator;

Fig. 6 is a view similar to Fig. 5 with the indexing mechanism actuated so as to move the carriage to its second position with the book holder and book gripped thereby rotated approximately 180° in clockwise direction from its position as shown in Fig. 5 so as to accurately position a second minor edge of the book parallel to the shear plane of the shear assembly;

Fig. 7 is a view similar to Figs. 5 and 6 with another embodiment of the indexing mechanism actuated so as to move the carriage to its third position with the book holder and book gripped thereby rotated approximately 90° in counterclockwise direction from its second position so as to accurately position a major edge of the book (i.e., the edge opposite the edge gripped by the holder) so as to be parallel to the shearing plane of the shearing assembly, where the indexing mechanism is actuated by a rodless hydraulic cylinder rather than the double rod hydraulic actuator, as shown in Fig. 5;

Fig. 8 is a top plan view of the trimmer, as shown in Fig. 3;

Fig. 9 is a side perspective view of the trimmer from the right side as it is shown in Fig. 7 illustrating the second embodiment of the indexing mechanism;

Fig. 10 is a front perspective view of the trimming mechanism shown in Figs. 7 – 9 with the carriage and holder in its first position;

Fig. 11 is a view similar to Fig. 10 with the carriage and the holder in its above said second position;

Fig. 12 is a schematic of the hydraulic system for the trimmer of the present invention;

Fig. 12A is a schematic for the stepper motor and screw jack that raises and lowers the carriage with respect to the shear plane;

Fig. 12B is a hydraulic schematic for the book clamp;

Fig. 12C is a hydraulic schematic for the shear mechanism;

Fig. 12D is a hydraulic schematic for the book and trash chute;

Fig. 13 is an electrical schematic for the trimmer;

5 Fig. 14 is a top plan view of the shear assembly; and

Fig. 15 is an end elevational view of the shear assembly.

Corresponding reference characters indicated corresponding parts throughout the several views of the drawings.

DESCRIPTION OF PREFERRED EMBODIMENT

Referring now to the drawings, and more particularly to Fig. 1, a book trimming apparatus of the present invention is indicated in its entirety at 1. The book trimmer comprises a frame 3 mounted on casters 5 so that the trimmer may readily be moved to convenient positions for trimming books, as required. Leveling screws 6 are also carried by frame 3 so that with the trimmer in a desired operating position, the leveling screws may be lowered to engage the floor thus solidly supporting the trimmer with respect to the floor. Trimmer 1 is enclosed by a cabinet 7. As indicated at 9, trimmer 1 has a work opening which allows an operator to readily place a book to be trimmed in the apparatus for being trimmed. As shown, work opening 9 is in the upper front portion of the cabinet 7 and the cabinet is provided with controls C for adjusting the finished size of the book to be trimmed and for initiating operation and for emergency stopping of apparatus 1. While controls C are shown to be mounted on control panels 11 on the sides of the work opening 9, it will be understood that within the broader aspects of this invention, such controls may be mounted at a convenient location on the trimmer such

that they are readily accessible by the operator. It will also be understood, that the opening 9 may be provided with a light curtain safety switch such that if the operator extends his hand through the opening while the trimmer is in operation, the trimmer will immediately stop. As shown, finger switches FS1 and FS 2 are provided at the top of 5 the cabinet. In order to start operation of the trimmer after the book has been installed, the operator must press both of the finger switches at the same time.

As noted, trimmer 1 is intended to trim the margins M of a perfect bound book B (as shown in Fig. 2) so as to produce a perfect bound book having predetermined finished dimensions. A perfect bound book is a document having a multiplicity of text pages P and a soft paper cover PC which is typically of a substantially thicker (heavier) stock than the text pages. Book B typically (though not necessarily) is of rectangular dimensions having a major dimension (height) and a minor dimension (width). Thus, the book has two minor edges (M1 and M2) and two major edges (M3 and spine S, as hereinafter described). Along one major edge of the book, the text pages P are bonded by a suitable adhesive to one another and to the inner face of the center portion of the cover PC in a manner well known to those skilled in the book binding art. The edge along which the pages are bound to the center portion of the cover is referred to as the spine S of the book. Thus, in order to produce a perfect bound book with uniform edges of predetermined height and width dimensions, the book is printed on stock somewhat 15 larger than the predetermined finished dimensions of the book and the excess margins M of the book along both of the minor edges M1 and M2 and along the major edge M3 opposite spine S are trimmed to predetermined dimensions so as to result in a trimmed 20 or finished book having predetermined major and minor edges. While the trimmer of the

present invention is described herein in the context of trimming three edges of a perfect bound book, those skilled in the art will appreciate that trimmer 1 may be used to trim one, two, three or four edges of documents other than books. In the above description of the book, the book is described as being rectangular having major and minor dimensions. However, those skilled in the art will recognize that the trimmer 1 may also be used to trim square shaped books as well as rectangular books. In such cases, the minor edges of the book M1 and M2 are perpendicular to spine S and the major dimension is parallel to the spine.

As shown in Figs. 3 and 4, trimmer 1 has a shear blade assembly 13 mounted on frame 3 substantially at the level of the lower edge of work opening 9. The shear assembly has a shear blade 15 which is forcefully movable in horizontal direction defining a shear plane SP (also referred to as a shearing plane) between an open or retracted position (as shown in dotted lines in Fig. 4) in which a book B (or other document) to be trimmed may be positioned between the cutting edge 17 of blade 15 and a stationary shear platen 19 and a closed or trimming position (as shown in solid lines in Fig. 4) in which the cutting edge 17 of blade 15 shears through the cover PC and text pages P of the book along the shearing plane SP. Shear blade 15 is forcefully moved between its open and closed positions by a suitable power drive, such as a hydraulic cylinder 21. Those skilled in the art will appreciate that power drives other than a fluid cylinder may be used to actuate the shear blade. For example, a screw jack or other mechanical drive may be employed. As best shown in Figs 14 and 15, shear assembly 13 operates through a plurality of inclined cams and corresponding cam followers that moves (translates) shear blade 15 between its open and closed positions

while remaining parallel to stationary shear platen 19. Further, the shear assembly include a book clamp 18 which forcefully holds the book in position against shear platen 19. This clamp is operated by a clamp cylinder 20. Thus, before the book is engaged by shear blade 15 to shear the book, it is clamped with respect to the platen by the 5 clamp and after shearing one edge of the book, the clamp is released to permit the book to be moved to its second and third positions as will be hereinafter described.

Figs. 14 and 15 illustrate the shear blade assembly 13 previously described. Of course, the reference characters of Figs. 14 and 15 correspond to the reference characters used in Figs. 1 – 10 and thus need not be described in regard to Figs. 14 and 15. As previously noted, the shear blade assembly operates through a series of inclined cams, as indicated at 201 in Figs. 14 and 15, and corresponding cam followers 203. Book clamp 18 also operates through cams 203 and corresponding cam followers 205.

In accordance with this invention, trimmer 1 further has a carriage 23 supported 15 on a pair of horizontal slide rods 25a, 25b. The carriage 23 is movable in horizontal direction relative to the shear blade 15 on these slide rods between a first position (as shown in Figs. 3 and 5) in which a first edge or margin (e.g., minor edge M1) of the book may be trimmed, to a second position (as shown in Fig. 6) in which a second edge or margin (e.g., the other minor edge M2) of the book may be trimmed, to a third 20 position (as shown in Fig. 7) in which a third edge or margin (e.g., major edge M3) of the book may be trimmed by shear blade 15.

Slide rods 25a, 25b are part of a subframe 27 which in turn is mounted on a pair

25 of vertically oriented slide rods 29a, 29b so that subframe 27 along with carriage 23 are

Sub-frame 27 is generally rectangular having upper and lower sills 37a, 37b and left and right stiles 39a, 39b with slide rails 25a, 25b rigidly secured to stiles 39a, 39b. Each of the vertical stiles 39a, 39b has a pair of slide bearings 41a, 41b mounted thereon with each pair of slide bearings slidingly receiving a respective vertical slide rail 29a, 29b. Carriage 23 is similarly provided with a pair of slide bearings 43a, 43b for slidingly receiving a respective slide rail 25a, 25b. It will be understood that the above noted slide bearings 41a, 41b and 43a, 43b have a close tolerance sliding fit with their corresponding slide rails 29a, 29b and 25a, 25b such that the carriage and the sub-frame are substantially constrained to only move in the axial direction of their respective slide rails.

An indexing mechanism, as generally indicated at 45, is carried by sub-frame 27 for accurately moving carriage 23 between its first, second and third positions (as heretofore described) and for rotating holder 35 such that first, second and third edges or margins M1 – M3 of the book are presented to shear blade 15 for trimming predetermined amounts from the edges of the book B so as to result in a finished or trimmed book of predetermined finished dimensions. As best shown in Fig. 5, indexing mechanism 45 is shown to comprise an actuator 47, preferably a two cylinder hydraulic actuator. Specifically, actuator 47 has a first rod end 49 pinned to with respect to sub-frame 27, as indicated at 50 (see Fig. 4), a cylinder body 51, and a second rod 53 pivotally coupled to a bell crank 55. Bell crank 55 has a first arm 57 having its free end pivotally connected to rod 53, as indicated at 59. The bell crank further has a second arm 61 rigidly connected to arm 57, as indicated at 63, such that arms 57 and 61 are rigidly fixed relative to one another such that the arms are roughly at an angle of about

120° relative to one another. The free end of arm 61 is pivotally connected to book holder 35, as indicated at 65 (see Fig. 4), in a manner as will be further described hereinafter. As indicated at 67, the center portion of bell crank 55 is pivotally secured to a stationary member 69 fixedly secured to lower sub-frame rail 37b.

5 More specifically, book holder 35 includes a plate 71 pivotally mounted on carriage 23 to pivot about a pivot point 73, as shown in Fig. 4. A pair of spacers 74 extend outwardly from plate 71 and an anvil 76 is carried thereby so as to be spaced from plate 71 such that the outer surface of the anvil is generally in the same vertical plane of the vertical face of shear platen 19 (see Fig. 4). A gripping actuator 77 (e.g., a selectively operable hydraulic or air cylinder) is supported by a rigid block 78 so as to be spaced outwardly from anvil 76. The actuator 77 preferably (but not necessarily) is a piston and cylinder fluid actuator having an actuator rod 80 (see Fig. 9) carrying a gripping plate 81. Upon actuation of actuator 77 (i.e., upon admitting a suitable fluid, such as air or hydraulic fluid, into the cylinder so as to effect movement of the piston in the cylinder), rod 80 (which is operatively connected to the piston) and gripping plate 81 carried by the rod are movable between a retracted position (as shown in Figs. 4 and 7) in which a book B to be trimmed may be placed within holder 35 and positioned between anvil 76 and gripping plate 81 and a closed or gripping position in which the gripping plate 81 forcefully presses the book B between the gripping plate and anvil 76
20 thereby to securely grip book B. It will be understood that with carriage 23 in its first position (see Fig. 5) and with the actuator 77 in its gripping position and with the book B gripped tightly between gripping plate 81 and anvil 76, one edge of book B is disposed

substantially in the same plane as the shearing plane SP between the edge of blade 15 and platen 19.

It will be further noted that shear 13 is provided with book guides 82 which aid an operator in inserting a book in holder 35 and guiding the cover and the pages of the book as it is inserting into the opening between blade 15 and shear platen 19. It will be understood that with the book B in position to be trimmed and with the carriage in its first position, as the carriage is moved to its second and third positions and as the book B is rotated so as to trim the second and third edges or margins of the book, at least a portion of the book remains within the opening between shear blade 15 and shear platen 19 and between guides 82 so that the pages and the covers of the book are maintained in a desired position to be sheared and so that the pages and the cover are not damaged as the carriage moves and as the book is rotated. As shown in Fig. 7, guides 82 are hingedly mounted with respect to the trimmer frame so that they are free to move in a vertical plane with the book as the shear blade 15 closes. This allows somewhat thinner books to be trimmed. After the edges of book B have been trimmed, actuator 77 may be operated to move the gripping plate 81 toward its retracted position thereby to release the trimmed book.

As shown in Figs. 5 and 7, sub-frame 27 has a pair of stops 83a, 83b for engagement by a respective lower horizontal surface of holder 35. That is, with carriage in its first position, as shown in Fig. 5, the lower horizontal surface 85 of holder 35 will be in engagement with its corresponding stop 83a thereby to insure that the carriage is substantially horizontal and to insure that the spine S of book B gripped by holder 35 is substantially vertical. This in turn will insure that the first minor edge M1 of

the book to be trimmed in the manner described above is substantially parallel to shear plane SP. Likewise, with carriage 23 in its second position, as shown in Fig. 6, another horizontal surface 87 on holder 35 will be in engagement with its respective stop 83b so as to insure that the holder is substantially horizontal and so that the other minor edge

5 M2 of book B is parallel to the shear plane SP.

Referring to Figs. 5 – 7, book holder 35 has a plate 71 which has a pin 91 extending therefrom toward shear 15. Member 37b of sub-frame 27 has a stationary center stop plate 93 rigidly affixed thereto and this stop plate has a V-shaped notch 95 in its upper edge, with this V notch being substantially centered relative to the movement of carriage 23 along slide rods 25a, 25b. As carriage 23 is moved from its second to its third position (as heretofore described) and as the holder 35 is rotated in counterclockwise direction approximately 90°, pin 91 is received in V notch 95 thereby to centrally locate the carriage along slide rods 25a, 25b. Also, with pin 91 received in V notch 95, bell crank 55 under the force of indexing actuator 45 exerts a downwardly acting force on carriage which tends to orient holder 35 such that the major edge M3 to be trimmed of book B gripped by the holder is substantially parallel to the shear plane SP. It will be understood that preferably, stops 83a, 83b may be provided with screw adjustments and elastomeric pads 97 to serve as the active elements of the stops engageable by horizontal surfaces 85, 87 thereby accurately position the minor edges

20 M1 and M2 of book B so as to be parallel to the shear plane SP so as to insure that upon actuation of shear assembly 13 that the trimmed minor edges of the book will be substantially parallel to one another.

As shown in Fig. 4, pivot 59 is offset from pivot 67. In accordance with this invention, it is preferred (but not required) that the pivots for the indexing mechanism or linkage be substantially co-planar, as shown in Figs. 7 – 11. In these last mentioned drawing figures, offset bell crank 55 of Figs. 3 – 6 has been replaced with a straight link 201 which, as indicated at 203 in Fig. 9, is pinned at one end to plate 71 which in turn is connected to carriage 23. The other end of link 201 is pinned, as indicated at 205, to a stationary block 207 mounted substantially mid-way between the ends of slide rods 25a, 25b. This link 201 causes the book holder 35 to rotate with respect to carriage 23 as the latter moves between its first, second and third positions, as heretofore described. In place of actuator 47, the carriage 23 is forcefully driven by a rodless hydraulic cylinder 209, such as is commercially available from the Bimba Manufacturing Company of Monee, Illinois, under the trade designation as an Ultratran rodless cylinder (magnetically coupled). The rodless cylinder 209 is mounted on a slide rod 211 parallel and positioned below slide rod 25. The rodless cylinder 209 serves as a linear actuator for moving carriage 23 along slide rods 25a, 25b between its first, second and third positions. It will be understood that with the carriage 23 in its first position, as shown in Fig. 10, the rod holder 35 will be rotated in a first position in which it is in engagement with the left-hand stop 97 thereby to accurately orient a first edge M1 of the book B held by the book holder to be parallel to the shearing plane SP. Upon actuation of the rodless cylinder 209 to effect movement of carriage 23 from its first to its second position (as shown in Fig. 11), the rodless cylinder will effect sliding movement of carriage 23 along the full length of slide rods 23a, 23b, and the body of the book holder 35 will be in engagement with right-hand stop 97. Of course, as the carriage travels

along the slide rods 25a, 25b for its first position to its second position, the link 201 will cause the book holder 35 to rotate relative to carrier through an angle of about 180° and the book holder 35 will come into engagement with a respective stop 97 so as to position the second edge M2 of the book so as to be parallel to the shearing plane SP.

5 Then, after the second edge has been trimmed, as the carriage moves from its second to its third position, the link 201 will cause the book holder to rotate in reverse direction 90°. As the carriage and book holder move to their third position, a fluid cylinder 215 mounted on the back side of frame member 37b (see Fig. 11) may be actuated so as to extend its rod (not shown) with the later serving as a movable stop pin engageable by the carriage thereby to accurately locate the carriage in its third position with pin 91 received in V notch 95 of plate 93. In this manner the third edge M3 of the book positioned parallel to the shearing plane SP. Of course, it will be understood that with the book in the above-said first, second or third position, the carriage may be moved vertically on vertical slide rods 29a, 29b so as to vertically position the book relative to the shearing plane such that upon actuation of the blade 15, a predetermined amount of the book B along a respective edge will be trimmed.

15 As can best be seen in Figs. 3 and 4, the trash trimmed from the margins M1 – M3 or edges of book B by blade 15 is below the level of the blade such that as the trash (i.e., the excess margins along the edges of the book B, as shown by the dotted lines in Fig. 2), such that as the shear blade 15 cuts these excess margins from book B, the trash will fall by gravity downward. A suitable trash chutes or guides TG is provided below the level of shear blade 15 so as to direct the trash downwardly to a suitable trash container TC, as illustrated in Fig. 1.

As shown in Fig. 3, a diverter tray DT is provided below shear blade 15 so as to receive the excess margins trimmed from the book (such excess margins being referred to as trash) or to receive the trimmed book. The diverter tray DT is movable by means of a selectively actuatable fluid cylinder 301 (see Fig. 12D) between a trash receiving position in which the trash is directed so as to fall by gravity onto a trash tray TT which in turn directs the trash by gravity into trash container TC. Upon completing trimming of book B, diverter tray DT is shifted from its trash receiving position to a book delivery position in which a completed book released from book holder 35 will fall downwardly onto the diverter tray and be directed onto a horizontal surface which serves as a book delivery tray BT (see Fig. 1).

Preferably, trash container TC is a waste can supported on a slide out support such that the operator may readily remove the trash container so as to empty it and to place an empty trash container within the trimming apparatus 1 of this invention. In accordance with this invention, trash guide TG is selectively movable between a first position for directing the trash downwardly toward trash container TC, as described above, and a second position such that as a trimmed (finished) book B is released by book gripper 35 is released, the book will fall downwardly through shear assembly 13 onto the upper surface of the trash guide TG so that the book is directed onto a horizontal book table BT below the level of the shear assembly. As seen in Fig. 1, a book removal opening 10 is provided in the front of cabinet 7 below work opening 9 thereby to permit the operator to readily remove the finished book from the trimmer.

The kinematics of indexing mechanism 45 or the modified mechanism using rodless cylinder 209 may be more clearly understood from a description of its operation.

With carriage 23 in its first position, as shown in Fig. 5, the carriage is disposed toward one end (the left end, as shown in Fig. 5) of slide rods 25a, 25b, and actuator 45 is in a condition where both rods 49 and 53 are extended such that bell crank 55 is positioned such that arm 61 is in its leftmost position. With rodless cylinder 209, it is actuated such 5 that the carriage 23 is at the left-hand ends of the slide rods 25a, 25b, as shown in Fig. 7. This in turn positions holder 35 such that a book B may be inserted therein for being gripped by gripping actuator 77 along the spine of the book substantially midway between the minor edges M1 and M2 of the book with one of the minor edges of the book (e.g., edge or margin M1) facing downwardly and being disposed substantially parallel to the horizontal shear plane SP of shear 13. With this first minor edge being so disposed such that it is parallel to shear plane SP, stepper motor 33 under the control of a control system CS is energized so as to rotate screw jack 31 a predetermined amount to raise or lower sub-frame 27 on vertical slide rods 29a, 29b so as to position this first minor edge of book B is a predetermined location with respect to the shear plane so that 15 upon actuation of shear assembly 13, a predetermined amount of the margin M of the book B along this first minor edge is trimmed from the book. After this first minor edge or margin of book B gripped by gripping actuator 77 has been trimmed to a predetermined dimension, actuator 45 is actuated such that rod 49 is retracted into the actuator body 47 thus causing arm 57 of bell crank 55 to rotate clockwise (as shown in 20 Fig. 6) about pivot point 67 such that the carriage 23 is slid along slide rods 25a, 25b from the left side of sub-frame 27 to the right side. In the case of rodless cylinder 209, it is actuated to effect movement of the carriage from its first position to its second position (as shown in Fig. 11). When moved from its first to its second position either

by actuator 45 or by rodless cylinder 209, holder 35 is rotated through an angle of about 180° such that the other minor edge M2 of book B is disposed downwardly toward shear blade 15 such that this other minor edge is substantially parallel to shear plane SP. Again, stepper motor 33 is actuated under the control of control system CS so as effect 5 rotation of screw jack 31 so as to accurately vertically position book B with respect to the shear plane SP such that a predetermined amount of the book along this second minor edge will be trimmed upon actuation of the shear assembly 13 by control system CS. After the second minor edge has been trimmed to its predetermined dimension, control system CS effects actuation of indexing actuator 45 such that both rods 49 and 53 are retracted into actuator body 51 thereby to effect rotation of bell crank 55 about pivot point 67 thereby to move carriage 23 to its third position in which the carriage is located substantially centered between the ends of slide rods 25a, 25b. Of course, the control system CS may also actuate rodless cylinder 209 to move the carriage to its third position (see Fig. 10). As the carriage is moved to its third position by either actuator 45 or by rodless cylinder 209, holder 35 along with book B held thereby is rotated approximately 90° in counterclockwise direction (as viewed in Fig. 6) such that the major edge M3 of the book B opposite the spine S (which is gripped by gripping actuator 79) is disposed parallel to shear plane SP. Again, under the control of control system CS, stepper motor 33 is energized so to effect rotation of screw jack 31 to in 20 turn raise or lower sub-frame 27 on vertical slide rods 29a, 29b so that a predetermined amount of the excess margin of the book along this major edge M3 is positioned below the level of shear plane SP such that upon actuation of shear assembly 13, shear blade 15 will trim this margin M3 from the book. Upon completion of this trimming operation,

shear blade 15 will be retracted (opened) and the trimmed book will be released by gripping actuator 77 so as to fall downward through shear assembly 13 for discharge from the trimming apparatus. It will be understood that stepper motor 33 and screw drive 31 cooperate to result in relatively small increments of vertical movement of carriage 23 along with book B held in holder 35 toward and away from the shear plane SP of shear blade 15. For example, the book may be moved in increments as small as 1/1000th (0.001) inches.

Referring now to Fig. 12, a hydraulic schematic diagram is shown for operating the various hydraulic cylinders heretofore described in a manner well known to those skilled in the art.

Fig. 12A is a diagrammatic view illustrating the stepper motor 33 operating through screw jack 33 to raise and lower carriage 23 on vertical slide rods 29a, 29b for vertically moving an edge of the book B toward and away from the shear plane SP. Also shown is the rodless cylinder 209 which effects horizontal movement of carriage 23 along slide rods 25a, 25b.

Fig. 12B illustrates book clamp cylinder 77.

Fig. 12C illustrates clamp cylinder 20 and shear cylinder 21.

Fig. 12D illustrates diverter tray fluid cylinder 301 which is operatively connected to diverter tray DT for hingedly moving the diverter tray between its trash receiving and book discharge positions.

Fig. 13 is an electrical schematic of the trimmer of the present invention. The trimmer is controlled by a suitable programmable process controller, such as the heretofore described RPC 52 process controller. The program for controlling operation

of the trimmer is set out below. From this disclosure, one skilled in the art could readily make and use the trimmer herein disclosed.

It will be noted that the adjustable voltage elements V1 – V3 are used to set the dimensions of the book to be trimmed. For example, these could be rotary 5 potentiometers. However, in a more preferred form, these adjustable voltage elements are better converted to a digital keypad which an operator may use to enter the dimensions of the book. The code, as set forth below, does in fact employ such a digital keypad to enter the dimensions of the book.

It will be appreciated by those skilled in the art that while the apparatus of the present invention has been described to trim two minor edges and one major edge of book B, the apparatus of the present invention could readily be used to trim two major edges and one minor edge.

Those skilled in the art will recognize that the above code is merely a currently preferred example of how the control system CS may be programmed. However, it will be understood that if different controllers or different computer languages are used, or if a different programmer is consulted, entirely different code may be written to carry out the present invention.

In view of the above, it will be seen that the several objects and features of this invention are achieved and other advantageous results attained.

As various changes could be made in the above constructions and methods without departing from the scope of the invention, it is intended that all matter contained in the above description or shown in the accompanying drawings shall be interpreted as illustrative and not in a limiting sense.
